Abstract
Nonlinear coupled mode equations occur as universal modulation equations in various circumstances. It is the purpose of this paper to prove exact estimates between the approximations obtained via the nonlinear coupled mode equations and solutions of the original parabolic or hyperbolic systems. The models which we consider contain all difficulties which have to be overcome in the general case.

1 Introduction

Nonlinear partial differential equations on spatially extended domains are very often described by simpler models, so called amplitude or modulation equations. These equations can be derived by formal multiple scaling perturbation analysis. Typical examples of such universal modulation equations are the Ginzburg-Landau equation, the Nonlinear Schrödinger equation, or the Korteweg de Vries equation.

A very long time the formal derivation has been the only connection to the original systems. Only in the last years mathematicians started to analyze the question whether solutions of the original systems really can be described by the formally derived modulation equations, see [2, 7, 1, 16, 4, 10]. Interestingly it turned out that this is in general not true. There are counterexamples [11, 5], where the original system behaves differently than predicted by the formally derived modulation equations.

Motivated by [6], the subject of this paper is the mathematical justification of the so called nonlinear coupled mode equations (NLCME)

\[
\begin{align*}
\partial_T A_+ &= +v_g \partial_X A_+ + \alpha A_+ + \kappa A_- + (\gamma_1 |A_+|^2 + \gamma_2 |A_-|^2)A_+, \\
\partial_T A_- &= -v_g \partial_X A_- + \alpha A_- + \kappa A_+ + (\gamma_2 |A_+|^2 + \gamma_1 |A_-|^2)A_-,
\end{align*}
\]

(1.1)
in case of quadratic terms present in the original system. Herein, \( A_{\pm}(X, T) \in \mathbb{C} \), \( 0 \neq v_{g} \in \mathbb{R} \), \( T \geq 0 \), \( X \in \mathbb{R} \), and \( \alpha, \kappa, \gamma_{1,2} \in \mathbb{C} \). Solutions \( u \) of the original systems can be described by

\[
 u(x,t) = \varepsilon A_{+}(\varepsilon^{2}x, \varepsilon^{2}t)\varphi_{+}e^{ik_{0}x+i\omega_{0}t} + \varepsilon A_{-}(\varepsilon^{2}x, \varepsilon^{2}t)\varphi_{-}e^{-ik_{0}x+i\omega_{0}t} + \text{c.c.} + \mathcal{O}(\varepsilon^{2})
\]

with \( 0 \neq k_{0} \in \mathbb{R} \), \( 0 \neq \omega_{0} \in \mathbb{R} \), \( x \in \mathbb{R} \), \( t \geq 0 \), with \( \varphi_{\pm} \) in a Hilbert space, where c.c. means complex conjugate and where \( 0 < \varepsilon \ll 1 \) is a small parameter.

The NLCME appear for instance in the nonlinear propagation of light in an optical fiber waveguide with an underlying spatially periodic structure [6]. In case of \( \alpha = 0 \) and \( \kappa, \gamma_{1,2} \in \mathbb{R} \) they possess so called gap soliton solutions which play a big role in nonlinear optics.

As already said it is the purpose of this paper to prove exact estimates between the approximations obtained via the NLCME and solutions of the original systems. In order to keep the notations on a reasonable level we refrain from greatest generality and consider two special model problems as original systems which contain all difficulties which have to be solved in the general case. This has to be understood in the following sense. The NLCME are justified as a modulation equation if the dynamics in the original system can be predicted by the NLCME. This means that to solutions of the NLCME for \( T \in [0, T_{0}] \) there should be solutions of the original system for \( t \in [0, T_{0}/\varepsilon^{2}] \) which can be approximated via the NLCME. Since these solutions are of order \( \mathcal{O}(\varepsilon) \), Gronwall’s inequality only gives error estimates on time scales \( \mathcal{O}(1/\varepsilon) \) if quadratic terms are present in the original system. If the nonlinearity starts with cubic terms Gronwall’s inequality gives estimates on the right time scale \( \mathcal{O}(1/\varepsilon^{2}) \). This has been used in [6], where the NLCME have already been justified as a modulation equation for the equations of nonlinear propagation of light in an optical fiber waveguide with an underlying spatially periodic structure.

From a perturbation theoretical point of view the handling of quadratic nonlinearities considered in this paper is the real challenge. In this sense our methods apply to the general case.

We have to distinguish hyperbolic and parabolic systems. In hyperbolic systems the required time scale can be obtained with the help of a normal form transform. See Section 2. In the parabolic case the required time scale can be obtained by using the smoothing properties of the linear semigroup and by controlling the nonlinear mode interactions. See Section 3.

By the results of this paper it is clear that the NLCME provide good approximations of the dynamics in the original systems and do not have to be added to the counter examples of not useful modulation equations.
Notation. Throughout this paper we assume $0 < \varepsilon \ll 1$ and denote many different constants uniformly by $C$ if they can be chosen independent of $0 < \varepsilon \ll 1$.

2 The nonlinear wave equation

In this section we consider the hyperbolic case. The easiest model problem with a quadratic nonlinearity is a Klein-Fock equation with a spatially periodic potential

$$\partial_t^2 u = \partial_x^2 u - u + 2\varepsilon^2 \kappa \cos(2k_0 x) u - u^2$$

with $x, t \in \mathbb{R}$, $u = u(x, t) \in \mathbb{R}$, $\kappa, k_0 \in \mathbb{R}$. This equation is a simplified purely phenomenological version of a system of nonlinear partial differential equations considered in [6] describing the nonlinear propagation of light in an optical fiber waveguide with an underlying spatially periodic structure. In [6] for the more complicated system, but without quadratic terms, it already has been shown that the NLCME provide good approximations of the solutions of the original system.

It is the purpose of this section to show that this is also true in the case of quadratic terms present in the nonlinearity, when as explained in Section 1, an application of Gronwall’s inequality is not sufficient to obtain the required error estimates.

The method we use goes back to [7], where the validity question for the Nonlinear Schrödinger equation has been handled using averaging methods. A similar problem has been solved in [12] with the help of a normal form transform. By this method all quadratic terms can be eliminated such that after the transformation the proof for the cubic nonlinearities becomes applicable. In order to get rid of the quadratic terms the original system has to satisfy some non-resonance condition, see (2.13) below. In the same way we proceed for the validity question of the NLCME.

In the Nonlinear Schrödinger case there are no terms for the interaction of the counter propagating wave packets in lowest order. See [9]. For the NLCME the interaction term for the counter propagating spatially localized wave packets is of leading order and has to be included into the NLCME.

2.1 Derivation of the NLCME

In order to derive the NLCME we let $X = \varepsilon^2 x$, $T = \varepsilon^2 t$ and make the (preliminary) ansatz $u(x, t) = \varepsilon \Psi_1(x, t, \varepsilon)$ with

$$\varepsilon \Psi_1(x, t, \varepsilon) = \varepsilon A_1(X, T)E F + \varepsilon^2 A_2(X, T)E^2 F^2 + \frac{1}{2} \varepsilon^2 A_0(X, T)E^0 F^0$$

$$+ \varepsilon B_1(X, T)E^{-1} F + \varepsilon^2 B_2(X, T)E^{-2} F^2$$

$$+ \varepsilon^2 E_2(X, T)E^2 + \varepsilon^2 F_2(X, T)F^2 + \text{c.c.},$$

(2.2)
where $E = e^{ik_0 x}$ such that $2 \cos(2k_0 x) = E^2 + E^{-2}$, and $F = e^{i\omega_0 t}$ with $\omega_0 = \sqrt{k_0^2 + 1}$ determined by the linear dispersion relation for (2.1). Inserting (2.2) into (2.1) gives

\[
0 = \varepsilon^2[4(\omega_0^2 - k_0^2)A_2 - A_2 - A_1^2]E^2F^2 + \varepsilon^2[4(\omega_0^2 - k_0^2)B_2 - B_2 - B_1^2]E^{-2}F^2
+\varepsilon^2[-2A_1 B_1 - (1 - 4\omega_0^2)F_2]E^2F + \varepsilon^2[-2A_1 B_1 - (1 + 4k_0^2)E_2]E^2
+\varepsilon^2[-2i\omega_0 \partial_T A_1 + 2ik_0 \partial_X A_1 + \kappa B_1]
- 2A_0 A_1 - 2A_2 A_1 - 2B_1 E_2 - 2B_1 F_2]E^2F
+\varepsilon^3[-2i\omega_0 \partial_T B_1 - 2ik_0 \partial_X B_1 + \kappa A_1]
- 2A_0 B_1 - 2B_2 B_1 - 2A_1 E_2 - 2A_1 F_2]E^{-1}F
+\varepsilon^3[\kappa B_1 - 2A_1 B_2 - 2B_1 E_2 - 2A_1 F_2]E^{-3}F + \varepsilon^3[\kappa A_1 - 2A_2 B_1 - 2A_1 E_2]E^3F
+\varepsilon^3[-2A_2 B_2]E^{-3}F^3 + \varepsilon^3[-2A_1 A_2]E^3F^3 + \text{c.c.} + \mathcal{O}(\varepsilon^4),
\]

where $A_{-k} = \overline{A}_k$, $B_{-k} = \overline{B}_k$, $E_{-k} = \overline{E}_k$, $F_{-k} = \overline{F}_k$, and where we used

\[
\partial_t^2 (B(\varepsilon^2 x, \varepsilon^2 t)E^pF^q) = (\varepsilon^4 \partial_t^2 B(X, T) + 2i\omega_0 \varepsilon^2 \partial_T B(X, T) - \omega_0^2 \varepsilon^2 B(X, T))E^pF^q
\]

and similarly for $\partial_x^2$. Equating the coefficients of $\varepsilon^2 E^2F^2, \varepsilon^2 E^{-2}F^2, \varepsilon^2 E^0F^0, \varepsilon^2 F^2$ and $\varepsilon^2 E^2$ to zero and using $\omega_0^2 - k_0^2 = 1$ gives

\[
A_2 = \frac{1}{3} A_1^2, \quad B_2 = \frac{1}{3} B_1^2, \quad A_0 = 2(|A_1|^2 + |B_1|^2),
F_2 = \frac{-2}{1 + 4k_0^2} A_1 B_1, \quad E_2 = \frac{-2}{1 + 4k_0^2} A_1 B_1.
\]

Inserting this into the coefficients of $\varepsilon^3 E F$ and $\varepsilon^3 E^{-1} F$ we obtain

\[
-2i\omega_0 \partial_T A_1 + 2ik_0 \partial_x A_1 + \kappa B_1
- 2(2|A_1|^2 + |B_1|^2)A_1 - \frac{2}{3}|A_1|^2 A_1 + 4 \left( \frac{1}{1 + 4k_0^2} + \frac{1}{1 - 4k_0^2} \right) |B_1|^2 A_1 = 0,
-2i\omega_0 \partial_T B_1 - 2ik_0 \partial_x B_1 + \kappa A_1
- 2(2|B_1|^2 + |A_1|^2)B_1 - \frac{2}{3}|B_1|^2 B_1 + 4 \left( \frac{1}{1 + 4k_0^2} + \frac{1}{1 - 4k_0^2} \right) |A_1|^2 B_1 = 0,
\]

i.e., the NLCME with

\[
v_g = k_0/\omega_0, \quad \gamma_1 = \frac{7}{3} \omega_0 \quad \text{and} \quad \gamma_2 = \frac{1}{\omega_0} \left( 1 - 2 \left( \frac{1}{1 + 4k_0^2} + \frac{1}{1 - 4k_0^2} \right) \right).
\]

**2.2 The approximation result**

As a number of counterexamples [11, 5] show, it is not obvious that the dynamics of (2.1) can be predicted by the formally derived system (2.5). We show the following result.
Theorem 2.1 Let \((A_1, B_1) \in C([0, T_0], [H^3(\mathbb{R}, \mathbb{C})]^2)\) be solutions of the NLCME (2.5) for a fixed \(T_0 > 0\). Then there exist \(\varepsilon_0, C > 0\) such that for all \(\varepsilon \in (0, \varepsilon_0)\) there exist solutions \(u\) of (2.1) which can be approximated by

\[
\varepsilon \Psi_0(x, t, \varepsilon) = \varepsilon A_1(\varepsilon^2 x, \varepsilon^2 t)E F + \varepsilon B_1(\varepsilon^2 x, \varepsilon^2 t)E^{-1} F + c.c.
\]

such that

\[
\sup_{\varepsilon \in [0, T_0/\varepsilon^2]} \| u(\cdot, t) - \varepsilon \Psi_0(\cdot, t, \varepsilon) \|_{C^k_x} \leq C \varepsilon^2.
\]

Remark. The error of order \(O(\varepsilon^2)\) is small compared with the solution and the approximation which are both of order \(O(\varepsilon)\) for all \(0 \leq t \leq T_0/\varepsilon^2\), i.e., the dynamics predicted by the NLCME (2.5) can be seen in (2.1).

Proof. We write the solution \(u\) as a sum of an approximation \(\varepsilon \Psi\) and an error \(\varepsilon^2 R\). Then the error is determined by the equation

\[
\partial_t^2 R = \partial_x^2 R - R + 2\varepsilon^2 \kappa \cos(2k_0 x) R - 2\varepsilon \Psi R - \varepsilon^2 R^2 + \varepsilon^{-2} \text{Res}(\varepsilon \Psi),
\]

where the residual \(\text{Res}(\varepsilon \Psi)\) is defined by all terms which do not cancel after inserting the ansatz into (2.1), i.e.

\[
\text{Res}(u) = -\partial_t^2 u + \partial_x^2 u - u + 2\varepsilon^2 \kappa \cos(2k_0 x) u - u^2.
\]

It is easy to see that for \(f = O(1)\) the inhomogeneous equation

\[
\partial_t^2 R = \partial_x^2 R - R + \varepsilon^2 f
\]

has \(O(1)\)-bounded solutions \(R\) for all \(t\) on a time scale of order \(O(1/\varepsilon^2)\). Thus there are two difficulties which have to be overcome in order to prove the \(O(1)\)-boundedness of the error \(R\). We have to

a) prove that the residual \(\text{Res}(\varepsilon \Psi)\) is of order \(O(\varepsilon^4)\),

b) control the influence of the term \(2\varepsilon \Psi R\).

We start with the goal in a) which can always be achieved by adding higher order terms to the approximation defined in (2.2). We define the final approximation

\[
\varepsilon \Psi_2(x, t) = \varepsilon A_1(X, T)E F + \varepsilon^2 A_2(X, T)E^2 F^2 + \frac{1}{2} \varepsilon^2 A_0(X, T)E^0 F^0
\]

\[
+ \varepsilon B_1(X, T)E^{-1} F + \varepsilon^2 B_2(X, T)E^{-2} F^2 + \varepsilon^2 E_2(X, T)E F^2 + \varepsilon^2 E_1(X, T)F^2
\]

\[
+ \varepsilon^3 H_{-3,1}(X, T)E^{-3} F + \varepsilon^3 H_{3,1}(X, T)E^3 F + \varepsilon^3 H_{-1,3}(X, T)E^{-3} F + \varepsilon^3 H_{1,3}(X, T)E^3 F + c.c.
\]

\[2.7\]
where $A_1, B_1$ solve (2.5), where $A_0, A_2, B_2$ solve (2.4), and where $H_{-3,1}, H_{3,1}, H_{-1,3}, H_{1,3}, H_{-3,3}, H_{3,3}$ solve

$$
\varepsilon^3 \mathbf{E}^{-3} \mathbf{F} : (\omega_0^2 - 9k_0^2 - 1)H_{-3,1} + \kappa B_1 - 2A_1 B_2 - 2B_1 E_2
\tag{2.8}
= -8k_0^2 H_{-3,1} + \kappa B_1 - 2A_1 B_2 - 2B_1 E_2 = 0,
$$

$$
\varepsilon^3 \mathbf{E}^3 \mathbf{F} : (\omega_0^2 - 9k_0^2 - 1)H_{3,1} + \kappa A_1 - 2A_2 B_1 - 2A_1 E_2
\tag{2.8}
= -8k_0^2 H_{3,1} + \kappa A_1 - 2A_2 B_1 - 2A_1 E_2 = 0,
$$

$$
\varepsilon^3 \mathbf{E}^{-1} \mathbf{F}^3 : (9\omega_0^2 - k_0^2 - 1)H_{-1,3} - 2A_1 B_2 - 2B_1 F_2
\tag{2.8}
= 8\omega_0^2 H_{-1,3} - 2A_1 B_2 - 2B_1 F_2 = 0,
$$

$$
\varepsilon^3 \mathbf{E}^4 \mathbf{F}^3 : (9\omega_0^2 - k_0^2 - 1)H_{1,3} - 2A_2 B_1 - 2A_1 F_2
\tag{2.8}
= 8\omega_0^2 H_{1,3} - 2A_2 B_1 - 2A_1 F_2 = 0,
$$

$$
\varepsilon^3 \mathbf{E}^{-3} \mathbf{F}^3 : (9\omega_0^2 - k_0^2 - 1)H_{-3,3} - 2B_1 B_2 = 8H_{-3,3} - 2B_1 B_2 = 0,
\tag{2.8}
$$

$$
\varepsilon^3 \mathbf{E}^3 \mathbf{F}^3 : (9\omega_0^2 - k_0^2 - 1)H_{3,3} - 2A_1 A_2 = 8H_{3,3} - 2A_1 A_2 = 0,
\tag{2.8}
$$

with $A_{-j} = \overline{A}_j$, $B_{-j} = \overline{B}_j$. Thus, by adding the terms $H_{i,j}$ to the original ansatz all terms of order $O(\varepsilon^3)$ in the original residual can be eliminated, and so the final residual will be of order $O(\varepsilon^4)$.

To formulate and prove this rigorously we have to choose some function spaces. We consider (2.1) in Fourier-space and look for solutions in $L^1(\mathbb{R}, \mathbb{C})$. In the following we usually simply write $L^1(\mathbb{R})$ for both real and complex valued functions, and similar for the other spaces appearing below. The choice of $L^1(\mathbb{R})$ is mainly motivated by the invariance of $L^1(\mathbb{R})$ with respect to scaling in the following sense; defining the scaling operator $S_\varepsilon$ by $(S_\varepsilon u)(x) = u(\varepsilon x)$, for the Fourier transform

$$
\hat{u}(k) = (\mathcal{F}u)(k) = \frac{1}{2\pi} \int u(x)e^{-ikx}dx
$$

of a scaled function we obtain

$$
\mathcal{F}(S_\varepsilon u) = \frac{1}{\varepsilon} S_{\frac{1}{\varepsilon}}(\mathcal{F}u) \quad \text{and} \quad \|\hat{u}\|_{L^1} = \|\frac{1}{\varepsilon} S_{\frac{1}{\varepsilon}} \hat{u}\|_{L^1}.
$$

Estimates for $\hat{u}$ in $L^1(\mathbb{R})$ transfer easily into physical space, since $\mathcal{F}^{-1}$ is continuous from $L^1(\mathbb{R})$ into $C_0^\infty(\mathbb{R})$ equipped with the sup-norm, i.e., $\|u\|_{C_0^\infty} \leq \|\hat{u}\|_{L^1}$, but not vice versa. We remark that in classical Sobolev spaces $H^m(\mathbb{R})$ we would loose too many powers in $\varepsilon$ since $\|S_\varepsilon A\|_{H^m} \leq C\varepsilon^{-1}\|A\|_{H^m}$.

Before we go on with the proof we recall some basic facts. Let

$$
\|\hat{u}\|^p_{L^p(m)} = \int |\hat{u}(k)|^p(1 + |k|^2)^{pm}dk, \quad L^p(m) := \{\hat{u} \in L^p(\mathbb{R}) : \|\hat{u}\|_{L^p(m)} < \infty\}.
$$
Fourier transform is an isomorphism between $H^m(\mathbb{R})$ and $L^2(m)$, i.e., there exist constants $C_1, C_2 > 0$ such that $\|u\|_{H^m} \leq C_1 \|\hat{u}\|_{L^2(m)} \leq C_2 \|u\|_{H^m}$. Sobolev’s inequality is given by $\|\hat{u}\|_{L^1(m)} \leq C \|\hat{u}\|_{L^2(m+s)}$ for $s > \frac{1}{2}$ and a constant $C = C(s)$.

Multiplication in physical space corresponds in Fourier space to convolution

$$(\hat{u} \ast \hat{v})(k) = \int \hat{u}(k-l)\hat{v}(l) \, dl \quad \text{with} \quad \|\hat{u} \ast \hat{v}\|_{L^1} \leq \|\hat{u}\|_{L^1}\|\hat{v}\|_{L^1}.$$ 

With these estimates and the formal computation from above we may estimate the residual as follows.

**Lemma 2.2** Let $A_1, B_1 \in C([0, T_0], [H^3(\mathbb{R}, \mathbb{C})]^2)$ be solutions of (1.1). Define $A_2, B_2$ by (2.4) and $H_{i,j}$ by (2.8). Then there exist positive constants $C, \epsilon_0 > 0$ such that for all $\epsilon \in (0, \epsilon_0)$ the approximation $\Psi$ defined in (2.7) satisfies

$$\sup_{t \in [0, T_0/\epsilon^2]} \|\mathcal{F}\epsilon\Psi_2(\cdot, t)\|_{L^1} < C \epsilon \quad \text{and} \quad \sup_{t \in [0, T_0/\epsilon^2]} \|\mathcal{F}(\text{Res}(\epsilon\Psi_2(\cdot, t)))\|_{L^1} < C \epsilon^4.$$ 

Thus we have shown a) of the above program. In order to establish b) we consider (2.1) in Fourier space, i.e.

$$\partial^2_t \hat{u}(k) = (-k^2 - 1)\hat{u}(k) + \kappa [\epsilon^2 \hat{u}(k + 2) + \epsilon^2 \hat{u}(k - 2)] - \hat{u} \ast \hat{u}(k). \quad (2.9)$$

To eliminate the term $-2\epsilon^2\Psi R$ in (2.6) we use a normal form transform. Due to the special structure of (2.1) it is possible to eliminate the quadratic terms in (2.1) completely. This has been observed in [14] and used since this time for different purposes. However, for the validity proof there is no need for the complete elimination of all quadratic terms, see [12].

We formulate (2.9) as a first order system

$$\partial_t \hat{u} = L \hat{u} + \hat{N}(\hat{u}), \quad (2.10)$$

$$\hat{u} = \left( \begin{array}{c} \hat{u}_1 \\ \hat{u}_2 \end{array} \right) = \left( \begin{array}{c} \hat{u} \\ \frac{1}{\sqrt{k^2 + 1}} \partial_t \hat{u} \end{array} \right), \quad L = \left( \begin{array}{cc} 0 & \sqrt{k^2 + 1} \\ -\sqrt{k^2 + 1} & 0 \end{array} \right),$$

$$\hat{N}(\hat{u}) = \left( \begin{array}{c} 0 \\ \frac{1}{\sqrt{k^2 + 1}} (\kappa (\epsilon^2 \hat{u}_1(k - 2) + \epsilon^2 \hat{u}_1(k + 2)) - (\hat{u}_1 \ast \hat{u}_1)(k)) \end{array} \right).$$

Diagonalizing (2.10) by $\hat{u} = S \hat{v}$ with $S = \frac{1}{\sqrt{2}} \left( \begin{array}{cc} i & 1 \\ -1 & -i \end{array} \right)$ we obtain

$$\partial_t \hat{v} = M \hat{v} + \hat{N}(\hat{v}), \quad (2.11)$$

with

$$M = S^{-1} L S = \left( \begin{array}{cc} i \sqrt{k^2 + 1} & 0 \\ 0 & -i \sqrt{k^2 + 1} \end{array} \right), \quad \hat{N}(\hat{v}) = S^{-1} \hat{N}(S \hat{v}).$$
We write
\[ N(\dot{v}) = \varepsilon^2 N_1(\dot{v}) + N_2(\dot{v}, \dot{v}) \]
with \( N_1 \) linear in \( \dot{v} \) and \( N_2 \) containing the bilinear terms of \( N \) and make a near identity change of variables
\[ \dot{v} = \dot{w} + B(\dot{w}, \dot{w}) = T(\dot{w}) \]
with \( B \) an autonomous bilinear mapping. This gives
\[
\partial_t \dot{w} + B(\partial_t \dot{w}, \dot{w}) + B(\dot{w}, \partial_t \dot{w})
= M\dot{w} + MB(\dot{w}, \dot{w}) + \varepsilon^2 N_1(\dot{w} + B(\dot{w}, \dot{w})) + N_2(\dot{w}, \dot{w}) + O(\|\dot{w}\|^3)
\]
and so
\[
\partial_t \dot{w} = M\dot{w} + MB(\dot{w}, \dot{w}) - B(M\dot{w}, \dot{w}) - B(\dot{w}, M\dot{w}) + N_2(\dot{w}, \dot{w})
+ \varepsilon^2 N_1(\dot{w} + B(\dot{w}, \dot{w})) + O(\|\dot{w}\|^3).
\]
In order to eliminate the quadratic terms \( N_2(\dot{w}, \dot{w}) \) we have to find a \( B \) such that
\[ MB(\dot{w}, \dot{w}) - B(M\dot{w}, \dot{w}) - B(\dot{w}, M\dot{w}) + N_2(\dot{w}, \dot{w}) = 0. \]
With
\[
(N_2(\dot{w}, \dot{w}))_h = \sum_{i,j=1}^{2} \int n_{hpq}(k, k-\ell, \ell) \dot{w}_p(k-\ell) \dot{w}_q(\ell) \, d\ell,
\]
\[
(B(\dot{w}, \dot{w}))_h = \sum_{i,j=1}^{2} \int b_{hpq}(k, k-\ell, \ell) \dot{w}_p(k-\ell) \dot{w}_q(\ell) \, d\ell
\]
for the \( h \)-th component of \( N_2 \) and \( B \), \( \lambda_1(k) = -\lambda_2(k) = i\sqrt{k^2 + 1} \) and \( n_{hpq}, b_{hpq} \)
some coefficients we obtain the well known relation
\[
(\lambda_h(k) - \lambda_p(k-\ell) - \lambda_q(\ell))b_{hpq}(k, k-\ell, \ell) = n_{hpq}(k, k-\ell, \ell).
\]
This can be resolved with respect to \( b_{hpq} \) due to the non resonance property
\[
\inf_{h, p, q \in \{1, 2\}, k \in \mathbb{R}} |\lambda_h(k) - \lambda_p(k-\ell) - \lambda_q(\ell)| \geq 1 \tag{2.13}
\]
of the dispersion relation of (2.1). Since \( \sup_{k, \ell \in \mathbb{R}, p, q = 1, 2} |n_{hpq}(k, k-\ell, \ell)| < C < \infty \) we obtain
\[
\|(B(\dot{w}, \dot{w}))_h\|_{L^1} = \int \int \sum_{p, q = 1}^{2} |b_{hpq}(k, k-\ell, \ell) \dot{w}_p(k-\ell) \dot{w}_q(\ell)| \, d\ell \, dk
\leq \sup_{k, \ell \in \mathbb{R}, p, q = 1, 2} |n_{hpq}(k, k-\ell, \ell)| \int \int \sum_{p, q = 1}^{2} |\dot{w}_p(k-\ell) \dot{w}_q(\ell)| \, d\ell \, dk
\leq C\|\dot{w}\|_{L^1} \|\dot{w}\|_{L^1}. \]
Thus the transformation (2.12) can be resolved with respect to \( \tilde{w} \) for \( \| \tilde{w} \|_{L^1} \) sufficiently small. Therefore (2.11) transforms into

\[
\partial_t \tilde{w} = M \tilde{w} + N_3(\tilde{w})
\]

(2.14)

with a nonlinearity \( N_3 \) which satisfies

\[
\| N_3(\tilde{w}) \|_{L^1} \leq C \varepsilon^2 \| \tilde{w} \|_{L^1} + C \| \tilde{w} \|_{L^1}^2
\]

for a constant \( C \) if \( \| \tilde{w} \|_{L^1} < \delta \) for a fixed \( \delta > 0 \) sufficiently small independent of \( \varepsilon > 0 \).

We write a solution \( \tilde{w} \) of (2.14) as a sum of an approximation \( \varepsilon \tilde{\Psi} \) and an error \( \varepsilon^2 \hat{R} \). The approximation \( \varepsilon \tilde{\Psi} \) is defined by

\[
\varepsilon \tilde{\Psi} = T^{-1} S^{-1} \left( \frac{\mathcal{F} \Psi_2}{\mathcal{F} \Psi_2 / \sqrt{k^2 + 1}} \right)
\]

and satisfies the assertions of Lemma 2.2. Therefore the error \( R \) satisfies a differential equation of the form

\[
\partial_t R = MR + h(\varepsilon \tilde{\Psi}, R)
\]

with

\[
\| h(\varepsilon \tilde{\Psi}, R) \|_{L^1} \leq C_1 \varepsilon^2 \| R \|_{L^1} + C_2 \varepsilon^3 \| R \|_{L^1}^2 + C_{\text{Res}} \varepsilon^2,
\]

where the constants \( C_1 \) and \( C_{\text{Res}} \) (coming from the residual) are independent of \( \varepsilon \in (0, 1) \) and \( \| R \|_{L^1} \) and where \( C_2 \) is independent of \( \varepsilon \in (0, 1) \) but depends on \( C_{\text{max}} = \sup_{t \in [0,T_0/\varepsilon^2]} \| R(t) \|_{L^1} \). Choosing \( \varepsilon > 0 \) so small that \( C_2(C_{\text{max}})\varepsilon < 1 \) we obtain

\[
\| R(t) \|_{L^1} \leq C_{\text{Res}} e^{(C_1+1)T_0} =: C_{\text{max}}
\]

with the help of Gronwall’s inequality. Doing back all transformations and using

\[
\sup_{t \in [0,T_0/\varepsilon^2]} \| \varepsilon \tilde{\Psi}_2 - \varepsilon \tilde{\Psi}_0 \| = O(\varepsilon^2)
\]

shows the assertion of Theorem 2.1. \( \square \)

3 The Swift-Hohenberg model

In this section we consider the parabolic case. The easiest model problem with a quadratic nonlinearity is a system of coupled Swift-Hohenberg type equations

\[
\partial_t U = \Lambda U + c \begin{pmatrix} \partial_x u \\ -\partial_x v \end{pmatrix} + \varepsilon^2 \alpha_0 U + 2 \varepsilon^2 \kappa \sin(2x) \begin{pmatrix} u - v \\ v - u \end{pmatrix} + N(U, \partial_x U),
\]

(3.1)

where \( U = U(x, t) = \begin{pmatrix} u(x, t) \\ v(x, t) \end{pmatrix} \in \mathbb{R}^2 \), \( \Lambda U = \begin{pmatrix} -(1 + \partial_x^2)^2 u \\ -(1 + \partial_x^2)^2 v \end{pmatrix} \),
\( c > 0, \alpha_0, \kappa \in \mathbb{R} \), and where \( N \) is some quadratic nonlinearity with \((N_1, N_2) \mapsto (N_2, N_1)\) as \( x \mapsto -x \), such that \((u, v) \mapsto (v, u)\) as \( x \mapsto -x \) in (3.1). This system is a phenomenological model of a reflection symmetric, pattern forming system in a spatially periodic domain undergoing a Hopf-bifurcation at a non-zero wavenumber \( k_0 = 1 \), where \( 0 < \varepsilon \ll 1 \) is the small bifurcation parameter.

Setting
\[
e_1 = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, \quad e_2 = \begin{pmatrix} 0 \\ 1 \end{pmatrix},
\]
the constant coefficient linear part \( L_1 \) of (3.1) with
\[
L_1 U = \Lambda U + \varepsilon^2 \alpha_0 U + c \begin{pmatrix} \partial_x u \\ -\partial_x v \end{pmatrix},
\]
fulfills
\[
L_1 e^{ikx} e_j = \lambda_j(k) e_j,
\]
where
\[
\lambda_1(k) = -(1 - k^2)^2 + \kappa k + \alpha_0 \varepsilon^2, \quad \lambda_2(k) = -(1 - k^2)^2 - \kappa k + \alpha_0 \varepsilon^2.
\]
Therefore, the linear semigroup \( e^{iL_1} \) damps all modes \( e^{ikx} \hat{U}(k) \) except of the so-called critical modes with \(|k|\) in a small neighborhood of the critical wavenumber \( k_0 \). The basic idea used for proving the approximation result for the NLCME below is to separate the critical modes from the stable modes with \(||k| - 1| \geq 1/4\), and to control the quadratic mode interaction. This idea goes back to [10], where the validity question for the Ginzburg-Landau equation for quadratic nonlinearities has been handled. In order so see interesting effects of the spatially periodic coefficient \( 2\varepsilon^2 \kappa \sin(k_p x) \), its wavenumber \( k_p \) has to be in resonance with the critical wavenumber \( k_0 = 1 \), i.e. \( k_p = nk_0 \) for some \( n \in \mathbb{N} \). See, e.g., [3, 15]. Choosing \( n = 2 \) is the simplest possibility to obtain the NLCME.

A particular simple choice for \( N(U, \partial_x U) \) that leads to NLCME in the regime of gap solitons is
\[
N(U, \partial_x U) = f_1(u^2 + v^2) \begin{pmatrix} 1 \\ 1 \end{pmatrix} + f_2(u \partial_x u + v \partial_x v) \begin{pmatrix} 1 \\ -1 \end{pmatrix}
\]
with suitable coefficients \( f_1, f_2 \in \mathbb{R} \). For notational simplicity we will use this nonlinearity throughout.

**Remark.** For systems like (3.1) the long time dynamics of the bifurcating solutions can be described by a system of singularly coupled Ginzburg-Landau equations in which space scales as \( X = \varepsilon x \), see, e.g., [13]. If we consider the special class of
very long wave modulations \( X = \varepsilon^2 x \) of the most unstable pattern we arrive at the NLCME which describe some interesting transient dynamics in the original system before the Ginzburg–Landau equations take their role in the description of the solutions. This is sketched in Figure 1.

Figure 1: Sketches of the dynamics of (3.1). a) transient dynamics, envelope described by NLCME; b) example of asymptotic dynamics described by coupled Ginzburg–Landau equations.

### 3.1 Derivation of the NLCME

We let again \( E = e^{ix} \), \( F = e^{i\omega t} \), \( X = \varepsilon^2 x \), \( T = \varepsilon^2 t \). As before we start with a preliminary approximation

\[
\varepsilon \Psi_1(x, t) = [\varepsilon A_1(X, T)EF + \varepsilon^2 A_2(X, T)E^2F^2 + \frac{\varepsilon^2}{2} A_0(X, T)]e_1 + \frac{\varepsilon^2}{2} A_0(X, T)]e_2 + e^2 C_{-2,2} \varepsilon^{-2} F^2 e_1 + \varepsilon^2 D_{2,2} \varepsilon^2 F^2 e_2 + c.c. \tag{3.3}
\]

Inserting (3.3) into (3.1) gives

\[
0 = \frac{\varepsilon^2}{2} [-A_0 + 2f_1(|A|^2 + |B|^2)] E^0 F^0 e_1 + \frac{\varepsilon^2}{2} [-B_0 + 2f_1(|A|^2 + |B|^2)] E^0 F^0 e_2 + \varepsilon^2 [-9A_2 + (f_1 + if_2) A^2_1] E^2 F^2 e_1 + \varepsilon^2 [-9B_2 + (f_1 + if_2) B^2_1] E^2 F^2 e_2 + \varepsilon^2 C_{-2,2} \varepsilon^{-2} F^2 e_1 + \varepsilon^2 D_{2,2} \varepsilon^2 F^2 e_2 + \varepsilon^3 [-\partial_T A_1 + c \partial_X A_1 + \alpha_0 A_1 + i \kappa B_1 + (2f_1 + if_2)(A_0 A_1 + A_2 A_{-1})] EF e_1 \tag{3.4}
\]

11
Note that for the derivation of the NLCME (3.6) the terms $a_0 A_1 + (2 f_1 + i f_2)(B_0 B_1 + B_2 B_{-1}) | E^{-1} F e_2$
$+ a_1 (2 f_1 - i f_2)(B_0 B_1 + B_2 B_{-1}) | E^{-1} F e_1$
$+ a_2 (2 f_1 + i f_2)(B_0 A_1 + A_2 A_1) | E F e_2$
$+ a_3 [(2 f_1 - i f_2) C_{-2,2} A_1 + (2 f_1 + i f_2) D_{2,2} B_1] | E F^3 e_1$
$+ a_3 [(2 f_1 + i f_2) C_{-2,2} A_1 + (2 f_1 - i f_2) D_{2,2} B_1] | E F^3 e_2$
$+ a_3 [(2 f_1 - i f_2) C_{-2,2} A_0] | E^{-2} F^2 e_1 + a_3 [(2 f_1 + i f_2) D_{2,2} B_2] | E^2 F^2 e_1$
$+ a_3 [(2 f_1 + i f_2) C_{-2,2} A_0] | E^{-2} F^2 e_2 + a_3 [(2 f_1 - i f_2) D_{2,2} B_0] | E^2 F^2 e_2$
$+ a_3 [(2 f_1 + 3 i f_2) A_2 A_1] | E^3 F^3 e_1 + a_3 [(2 f_1 - 3 i f_2) B_2 B_1] | E^{-3} F^3 e_1$
$+ a_3 [(2 f_1 - 3 i f_2) A_2 A_2] | E^3 F^3 e_2 + a_3 [(2 f_1 + 3 i f_2) B_2 B_1] | E^{-3} F^3 e_2$
$+ a_3 [(2 f_1 + 3 i f_2) D_{2,2} B_{-1} - i \kappa A_1] | E^3 F e_1 + a_3 [(2 f_1 - 3 i f_2) C_{-2,2} A_{-1} - i \kappa A_1] | E^{-3} F e_1$
$+ a_3 [(2 f_1 - 3 i f_2) D_{2,2} B_{-1} - i \kappa A_1] | E^3 F e_2 + a_3 [(2 f_1 + 3 i f_2) C_{-2,2} A_{-1} - i \kappa A_1] | E^{-3} F e_2$

where $A_{-j} = \overline{A_j}$, $B_{-j} = \overline{B_j}$. In the seventh line the (preliminary) residual starts, see below. Solving for $A_0$ at $\varepsilon^2 e_1$, for $A_2$ at $\varepsilon^2 E^2 F^2 e_1$, for $B_0$ at $\varepsilon^2 e_2$, for $B_2$ at $\varepsilon^2 E^{-2} F^2 e_2$, for $C_{-2,2}$ at $\varepsilon^2 E^{-2} F^2 e_2$, and for $D_{2,2}$ at $\varepsilon^2 E^2 F^2 e_2$, i.e.,

$$A_0 = 2 f_1 (|A_1|^2 + |B_1|^2), \quad B_0 = 2 f_1 (|A_1|^2 + |B_1|^2), \quad A_2 = \frac{1}{5} (f_1 + i f_2) A_1^2 \quad \text{etc.,} \quad (3.5)$$

the order $O(\varepsilon^2)$ terms vanish. Inserting the results into the equations at $\varepsilon^3 E F$ and $\varepsilon^3 E^{-1} F$ we obtain the NLCME for $A_1, B_1$, i.e.,

$$\partial_T A_1 = c \partial_X A_1 + a_0 A_1 + i \kappa B_1 + (\gamma_1 |A_1|^2 + \gamma_2 |B_1|^2) A_1, \quad (3.6)$$

$$\partial_T B_1 = -c \partial_X B_1 + a_0 B_1 + i \kappa A_1 + (\gamma_1 |B_1|^2 + \gamma_2 |A_1|^2) B_1,$$

with

$$\gamma_1 = (2 f_1 + i f_2)(2 f_1 + \frac{1}{9}(f_1 + i f_2)), \quad \gamma_2 = 2 f_1 (2 f_1 + i f_2).$$

**Remark.** Note that for the derivation of the NLCME (3.6) the terms $\varepsilon^2 C_{-2,2} E^{-2} F^2 e_1$
and $\varepsilon^2 D_{2,2} E^2 F^2 e_2$ are not needed. However, they are needed to produce a formally consistent approximation, i.e., to remove the $O(\varepsilon^2)$ terms from the residual in (3.4). In general one would also need

$$\varepsilon^2 C_{-2,0} E^2 e_1, \quad \varepsilon^2 C_{0,2} F^2 e_1, \quad \varepsilon^2 D_{-2,0} E^{-2} e_2, \quad \varepsilon^2 D_{0,2} F^2 e_2 \quad (3.7)$$

in (3.3) to balance terms at $\varepsilon^2 E^2 e_1, \varepsilon^2 F^2 e_1, \varepsilon^2 E^{-2} e_2, \varepsilon^2 F^2 e_2$ in (3.4) generated by the quadratic nonlinearity. However, due to our special nonlinearity, i.e., since there is no $uv$ in (3.2), these terms are not generated. Thus we may omit the terms from (3.7) in (3.3).
3.2 The approximation result

In contrast to the hyperbolic equation (2.1) system (3.1) is dissipative and allows for bigger spaces concerning the local existence and uniqueness of solutions. Therefore, we consider (3.1) in uniformly local Sobolev spaces $H^m_{ul}(\mathbb{R})$, where again in the notation we usually do not distinguish between real or complex or vector valued functions. The Banach spaces $H^m_{ul}(\mathbb{R})$ contain all kinds of bounded functions and are defined as follows: fix the weight function $\rho(x) = 1/\cosh(x)$ and let

$$ L^2_{ul}(\mathbb{R}) = \{ u \in L^2_{loc}(\mathbb{R}) : \| u \|_{L^2_{ul}} < \infty \}, $$

$$ L^2_{ul}(\mathbb{R}) = \{ u \in L^2_{ul}(\mathbb{R}) : \| T_y u - u \|_{L^2_{ul}} \to 0 \text{ as } y \to 0 \}, $$

where $(T_y u)(x) = u(x - y)$. Then

$$ H^m_{ul}(\mathbb{R}) := \{ u \in L^2_{ul} : \partial^j u \in L^2_{ul} \text{ for } 0 \leq j \leq k \}. $$

(3.8)

Since the spaces $H^m_{ul}(\mathbb{R})$ are based on $L^2(\mathbb{R})$ the global existence of solutions for typical dissipative systems can be shown via Fourier transform methods and weighted energy estimates, see [10, 8]. Moreover we have the estimates

$$ \| S_\delta A \|_{L^2_{ul}} \leq \delta^{-1/2} \| A \|_{L^2_{ul}} \text{ and } \| S_\delta A \|_{H^1_{ul}} \leq C \| A \|_{H^1_{ul}}, $$

(3.9)

where as before $(S_\delta A)(x) = A(\delta x)$. In the first estimate the factor $\delta^{-1/2}$ is due to scaling, and the second estimates holds due to $\| S_\delta A \|_{L^2_{ul}} \leq C \| S_\delta A \|_{L^\infty} \leq C \| A \|_{L^\infty} \leq C \| A \|_{H^1_{ul}}$ and the scaling properties of the derivative. With these preparations our approximation result reads as follows.

**Theorem 3.1** Let $(A_1, B_1) \in C([0, T_0], [H^0_{ul}(\mathbb{R}, \mathbb{C})]^2)$ be solutions of the NLCME (2.5) for a fixed $T_0 > 0$. Then there exist $\varepsilon_0, C > 0$ such that for all $\varepsilon \in (0, \varepsilon_0)$ there exist solutions $u$ of (2.1) which can be approximated by

$$ \varepsilon \Psi_0(x, t, \varepsilon) = \varepsilon A_1(\varepsilon^2 x, \varepsilon^2 t) \mathbf{E} \mathbf{f}_1 + \varepsilon B_1(\varepsilon^2 x, \varepsilon^2 t) \mathbf{E}^{-1} \mathbf{f}_2 + \text{c.c.} $$

such that

$$ \sup_{[\varepsilon \in 0, T_0/\varepsilon^2]} \| U(\cdot, t) - \varepsilon \Psi_0(\cdot, t, \varepsilon) \|_{H^1_{ul}} \leq C \varepsilon^2. $$

**Proof.** As in section 2 we start with a brief formal discussion. We set

$$ L_2 U = 2\kappa \sin(2x) \begin{pmatrix} u-v \\ v-u \end{pmatrix}, $$

13
and write the nonlinearity as a symmetric bilinear form \( N_1(U, U) \), i.e.,

\[
N_1(U, V) = \frac{1}{2} [N(U, \partial_x V) + N(V, \partial_x U)].
\]

Letting \( U = \varepsilon \Psi + \varepsilon^2 R \), where \( \Psi \) will be close to \( \Psi_1 \), the error \( R \) fulfills

\[
\partial_t R = L_1 R + \varepsilon^2 L_2 R + 2\varepsilon N_1(\Psi, R) + \varepsilon^2 N_1(R, R) + \varepsilon^{-2} \text{Res}(\varepsilon \Psi),
\]

where

\[
\text{Res}(U) = -\partial_t U + L_1 U + \varepsilon^2 L_2 U + N_1(U, U).
\]

From the properties of the semigroup generated by \( L_1 \), see below, it follows that for \( f \in \mathcal{O}(1) \) the inhomogenous equation \( \partial_t R = L_1 R + \varepsilon^2 L_2 R + \varepsilon^2 f \) has \( \mathcal{O}(1) \)-bounded solutions \( R \) in \( H^1_{\text{ul}}(\mathbb{R}) \) for all \( t \) on a time scale of order \( \mathcal{O}(1/\varepsilon^2) \). Therefore, roughly speaking, we again have to

a) show that \( \|\text{Res}(\varepsilon \Psi)\|_{L^2_{\text{ul}}} \) is sufficiently small,

b) control the influence of the term \( 2\varepsilon N_1(\Psi, R) \).

In order to achieve a) and b) we use the method from [10] and introduce so called mode-filters to separate the critical from the stable modes.

However, first we modify our approximation \( \Psi_1 \) in such a way that in the residual of (3.4) all coefficients of \( \varepsilon^3 \mathbf{E}^{\pm 1} \mathbf{F}^j \), \( j = 1, 3 \) vanish, since these terms are critical modes. The remaining \( \mathcal{O}(\varepsilon^3) \) terms in the residual belong to damped modes and will be controlled using the mode filters. By a simple calculation we find that the coefficients of \( \varepsilon^3 \mathbf{E}^{\pm 1} \mathbf{F}^j \), \( j = 1, 3 \) vanish if we modify \( \Psi_1 \) to

\[
\varepsilon \Psi_2(x, t) = \varepsilon \Psi_1(x, t) + \varepsilon^3 [C_{-1,1} \mathbf{E}^{-1} \mathbf{F} + C_{-1,3} \mathbf{E}^{-1} \mathbf{F}^3 + C_{1,3} \mathbf{F} \mathbf{E}^3] e_1 + \varepsilon^3 [D_{1,1} \mathbf{E} \mathbf{F} + D_{-1,3} \mathbf{E}^{-1} \mathbf{F}^3 + D_{1,3} \mathbf{F} \mathbf{E}^3] e_2
\]

where \( C_{i,j}, D_{i,j} \) satisfy

\[
\begin{align*}
-2iC_{-1,1} + i\kappa A_{-1} + (2f_1 - if_2)(B_0 B_1 + B_2 B_{-1}) &= 0, \\
-2iD_{1,1} + i\kappa B_1 + (2f_1 - if_2)(A_0 A_1 + A_{-2} A_1) &= 0, \\
-4iC_{-1,3} + (2f_1 - if_2)C_{-2,2} A_1 &= 0, \\
-2iC_{1,3} + (2f_1 + if_2) D_{2,2} B_1 &= 0, \\
-2iD_{-1,3} + (2f_1 - if_2)C_{-2,2} A_1 &= 0, \\
-4iD_{1,3} + (2f_1 + if_2) C_{-2,2} A_1 &= 0.
\end{align*}
\]

Note that adding the \( \mathcal{O}(\varepsilon^3) \) terms to \( \Psi_1 \) does not change the remaining \( \mathcal{O}(\varepsilon^3) \) terms in (3.4).
For the mode filters we use multipliers: given a function \( \hat{M} \in L^\infty(\mathbb{R}, \mathbb{C}) \), we define a multiplier \( M : L^2(\mathbb{R}, \mathbb{R}) \rightarrow L^2(\mathbb{R}, \mathbb{R}) \) by multiplying \( \hat{u} \) with \( \hat{M} \), i.e.,
\[
Mu = \mathcal{F}^{-1}(\hat{M}\hat{u}).
\]
In typical examples \( \hat{M} \) is a characteristic function, or the symbol of a differential operator, see below. The following lemma shows that such multipliers extend to bounded operators in uniformly local Sobolev spaces.

**Lemma 3.2** [10, Lemma 5] Let \( m \in \mathbb{Z}, (1+|\cdot|^2)^{m/2}\hat{M}(\cdot) \in C^2(\mathbb{R}, \mathbb{C}) \) and \( q \in \mathbb{N} \). Then \( M \) extends to a bounded operator (denoted by the same symbol) \( M : H^q_{ul}(\mathbb{R}) \rightarrow H^{q+m}_{ul}(\mathbb{R}) \) with
\[
\|Mu\|_{H^{q+m}_{ul}} \leq C(q, m)\|1+|\cdot|\|^{m/2}\hat{M}(\cdot)\|_{C^2_{ul}}\|u\|_{H^q_{ul}}
\]
with \( C(q, m) \) independent of \( \hat{M} \).

Now the mode filters are defined as follows. Let \( \chi_0 : \mathbb{R} \rightarrow \mathbb{R} \) be a \( C^\infty \) function with
\[
\chi_0(k) = \begin{cases} 
1, & |k| \leq 1/8 \\
\in [0, 1], & 1/8 \leq |k| \leq 1/4 \\
0, & 1/4 \leq |k| 
\end{cases}
\]
and let \( E_0 \) be the multiplier formally defined by \( \chi_0 \). Similarly, define \( E_c \) by
\[
\chi_c(k) = \chi_0(1+k) + \chi_0(-1+k),
\]
and let \( E_s = \text{Id} - E_c \). We call \( E_c, E_s \) mode filters since they separate critical and stable modes. Since they are not projections it will be helpful to define auxiliary mode filters \( E^b_c \) and \( E^b_s \) by
\[
\chi^b_c = \chi_0((1+k)/2) + \chi_0((-1+k)/2), \quad \chi^b_s = 1 - \chi_0(2(1+k)) - \chi_0(2(-1+k)).
\]
Note that \( E^b_c E_c = E_c \) and \( E^b_s E_s = E_s \). Finally, for \( U = (u, v)^T \) let
\[
\mathcal{E}_c U = \begin{pmatrix} E_c u \\ E_c v \end{pmatrix}, \quad \mathcal{E}_s = \text{Id} - E_c, \quad \mathcal{E}^b_c U = \begin{pmatrix} E^b_c u \\ E^b_c v \end{pmatrix}, \quad \mathcal{E}^b_s = \begin{pmatrix} E^b_s u \\ E^b_s v \end{pmatrix}.
\]
We define our final approximation \( \Psi \) by applying \( E_0 \) to all \( A_j, B_j, C_{i,j}, D_{i,j} \) in \( \Psi_2 \), i.e.,
\[
\varepsilon\Psi(x, t) = \varepsilon[(E_0 S_{z^2} A_1)(T) EF + \varepsilon^2(E_0 S_{z^2} A_2)(T) E^2 F^2 + \ldots] e_1 + \ldots \quad (3.14)
\]
and assume that \( (A_1, B_1) \) fulfill the NLCME (3.6) and \( A_0, A_2, B_0, B_2, C_{-2,2}, D_{2,2}, \ldots \)
fulfill the auxiliary equations (3.5), (3.13) as before. In order to show that the filtered approximation \( \Psi \) is close to \( \Psi_2 \) and to control \( \text{Res}(\varepsilon\Psi) \) we need the following lemma that estimates multipliers acting on scaled functions.
Lemma 3.3 [10, Lemma 6] Let $m \in \mathbb{N}$ and $(1 + | \cdot |^2)^{-m/2} \tilde{M}(\cdot) \in C^2(\mathbb{R}, \mathbb{C})$. Then

$$
\| M[(S_{ul} U) e^{i k_0 x}] \|_{H_{ul}^{q-r}} \leq C(q, r, m) \| (1 + | \cdot |)^{-m/2} \tilde{M}(\delta(\cdot + k_0)) \| c_q \| S_{ul} \| _{L(H_{ul}^{q-m}, H_{ul}^{q-r})} \| U \|_{H_{ul}^q}.
$$

for all $q \geq r \geq m$, with $C(q, r, m)$ independent of $\tilde{M}$.

In particular, in the situation of Lemma 3.3 assume that $\tilde{M}(k_0 + k) = \mathcal{O}(|k|^s)$ as $k \to 0$ with $s \leq m$. Then [10, Lemma 7]

$$
\| (1 + | \cdot |^2)^{-m/2} \tilde{M}(\delta(k_0 + \cdot)) \| c_q = \mathcal{O}(\delta^s). \tag{3.15}
$$

Using Lemma 3.2 with $q = 4$, $r = 3$ and (3.15) we obtain

$$
\| \text{Id} - E_0 \| [(S_{ul} A) \mathcal{E} / \mathcal{F}] \|_{H_{ul}^1} \leq C \| \text{Id} - E_0 \| [(S_{ul} A) \mathcal{E}] \|_{H_{ul}^1}
\leq \| (1 + | \cdot |^2)^{-3/2}(1 - \chi_0(\varepsilon^2(j + \cdot))) \| c_q \| S_{ul} \| _{L(H_{ul}^{q-m}, H_{ul}^{q-r})} \| A \|_{H_{ul}^q} \leq C \varepsilon^6. \tag{3.16}
$$

This holds since $1 - \chi_0(\varepsilon^2(j + k)) \equiv 0$ for $|k + j| \leq 1/(8\varepsilon^2)$, for $\varepsilon$ sufficiently small. By (3.16) $\Psi$ is close to $\Psi_2$, i.e.

$$
\| \Psi_2 - \Psi \|_{H_{ul}^1} = \mathcal{O}(\varepsilon^6). \tag{3.17}
$$

To estimate $\| \text{Res}(\varepsilon \Psi) \|_{H_{ul}^1}$ we also need estimates of $(\text{Id} - E_0) [\partial_x (S_{ul} A) \mathcal{E} / \mathcal{F}]$. Using Lemma 3.3 with $q = 3$, $r = 2$ we obtain

$$
\| (\text{Id} - E_0) [\partial_x (S_{ul} A) \mathcal{E} / \mathcal{F}] \|_{H_{ul}^1} = \varepsilon^2 \| (\text{Id} - E_0) [(S_{ul} \partial X A) \mathcal{E} / \mathcal{F}] \|_{H_{ul}^1}
\leq \| (1 + | \cdot |^2)^{-2}(1 - \chi_0(\varepsilon^2(j + \cdot))) \| c_q \| S_{ul} \| _{L(H_{ul}^{q-m}, H_{ul}^{q-r})} \| \partial X A \|_{H_{ul}^q} \leq C \varepsilon^6, \tag{3.18}
$$

and similarly for higher order derivatives of $S_{ul} A$.

In order to achieve b) we now split the error into a critical part $\varepsilon^2 R_c$ and a stable part $\varepsilon^3 R_s$, i.e., we let

$$
\varepsilon^2 R = \varepsilon^2 R_c + \varepsilon^3 R_s \quad \text{with} \quad \mathcal{E}_c^h R_c = R_c \quad \text{and} \quad \mathcal{E}_s^h R_s = R_s.
$$

Moreover, we introduce

$$
\varepsilon \Psi_c = \varepsilon (E_0 S_{ul} A_1)(T)\mathcal{E} \mathcal{F} e_1 + \varepsilon (E_0 S_{ul} B_1)(T)\mathcal{E}^{-1} \mathcal{F} e_2 + \text{c.c.,}
$$

$$
\varepsilon^2 \Psi_s = \varepsilon \Psi_c - \varepsilon \Psi_c,
$$

such that $\varepsilon \Psi_c$ contains the lowest order critical modes and $\varepsilon^2 \Psi_s$ contains the stable modes and the $\mathcal{O}(\varepsilon^3)$ corrections of the critical modes. In fact, by (3.16) we have $\| \Psi_s \|_{H_{ul}^1} = \mathcal{O}(1)$. Inserting $U = \varepsilon \Psi_c + \varepsilon^2 \Psi_s + \varepsilon^2 R_c + \varepsilon^3 R_s$ into (3.1) gives

$$
\partial_t R_c + \varepsilon \partial_t R_s = L_1 R_c + \varepsilon L_1 R_s + \varepsilon^2 L_2 R_c + \varepsilon^3 L_3 R_s + 2\varepsilon N_2(\Psi_c, R_c)
+ \varepsilon^2 N_2(R_c, R_c) + \varepsilon^3 G_1(R) + \varepsilon^3 G_2(R) + \varepsilon^2 \text{Res}(\varepsilon \Psi), \tag{3.19}
$$

16
where
\[ G_1R = 2[N_2(\Psi_c, R_s) + N_2(\Psi_s, R_c)], \quad G_2(R) = N_2(R_s, 2\Psi_s + 2R_c + \varepsilon R_s). \]

The crucial feature of quadratic nonlinearities is that the quadratic interaction of critical modes generates only stable modes, i.e., for \( u, v \in H^1_{ul}(\mathbb{R}) \) we have
\[ E_cN(E^h_c u, E^h_c v) = 0, \quad (3.20) \]
where \( N : H^1_{ul}(\mathbb{R}) \times H^1_{ul}(\mathbb{R}) \rightarrow L^2_{ul}(\mathbb{R}) \) is some bilinear mapping. This follows from looking at the support of \( \mathcal{F}E^h_c u \), see [10, Lemma 9].

We define \( R_c \) and \( R_s \) to be the solutions of the system
\[
\begin{align*}
\partial_t R_c &= L_1 R_c + \varepsilon^2 \mathcal{E}_c(L_2 R_c + G_1 R) + \varepsilon^3 N_c(R) + \varepsilon^2 \delta_c, \\
\partial_t R_s &= L_1 R_s + L_s R_c + \varepsilon N_s(R) + \delta_s, \\
(R_c, R_s)|_{t=0} &= 0,
\end{align*}
\]
(3.21)
where
\[
\begin{align*}
N_c(R) &= \mathcal{E}_c(L_2 R_s + G_2(R)), \\
\delta_c &= \varepsilon^{-4} \mathcal{E}_c \text{Res}(\varepsilon \Psi), \\
L_s R_c &= 2 \mathcal{E}_s(N_2(\Psi_c, R_c)), \\
N_s(R) &= \mathcal{E}_s(L_2 R_c + G_1 R + N_2(R_c, R_c) + \varepsilon L_2 R_s + \varepsilon G_2(R)), \\
\delta_s &= \varepsilon^{-3} \mathcal{E}_s \text{Res}(\varepsilon \Psi).
\end{align*}
\]
If \((R_c, R_s)\) is a solution of (3.21), then \( R_c + \varepsilon R_s \) is a solution of (3.19). In the derivation of (3.21) we used
\[
E_cN_2(\Psi_c, R_c) = 0 \quad \text{and} \quad E_cN_2(R_c, R_c) = 0
\]
due to (3.20). Thus there are no order \( O(\varepsilon) \) terms linear in \( R_c \) and no order \( O(\varepsilon^2) \) terms nonlinear in \( R_c \) in the equation for the critical part \( R_c \) of the error. This corresponds to b) on page 14.

For the approximation \( \varepsilon \Psi_2 \) defined in (3.12) all terms at orders \( \varepsilon^3 \mathbf{E}^{\pm 1} \) in (3.4) vanish by construction, i.e., formally we have \( \mathcal{E}_c \text{Res}(\varepsilon \Psi_2) = O(\varepsilon^4) \). For the filtered approximation \( \varepsilon \Psi \) we obtain rigorously
\[
||\mathcal{E}_c \text{Res}(\varepsilon \Psi)||_{H^1_{ul}} = O(\varepsilon^4), \quad ||\mathcal{E}_s \text{Res}(\varepsilon \Psi)||_{H^1_{ul}} = O(\varepsilon^3), \quad (3.22)
\]
using (3.16) and (3.18). See also [10, Lemma 8] for a detailed proof of this result in a related problem. Basically, (3.22) corresponds to a) on page 14. The nonlinearity \( \tilde{N}(R) : H^1_{ul}(\mathbb{R}) \rightarrow L^2_{ul}(\mathbb{R}) \) with
\[
\tilde{N}(R) = (N_c(R), N_s(R)).
\]
17
is a sum of linear and bilinear terms and therefore locally Lipschitz. In order to solve (3.21), for \( j = 0, 1 \) we introduce the spaces

\[
\mathcal{H}^j = C([0, T_0/\varepsilon^2], [H_{ul}^j(\mathbb{R})]^2)
\]
with

\[
\|(R_c, R_s)\|_{\mathcal{H}^j} = \sup_{0 \leq t \leq T_0/\varepsilon^2} (\|R_c\|_{H_{ul}^j} + \|R_s\|_{H_{ul}^j}),
\]

inverting the linear part of (3.21) and applying a fixed point argument. By (3.22) we have

\[
\|(\delta_c, \delta_s)\|_{\mathcal{H}^j} = \mathcal{O}(1).
\]

Note that \( \mathcal{E}_c^h \) (resp. \( \mathcal{E}_s^h \)) leaves the equation for \( R_c \) (resp. \( R_s \)) invariant. Therefore we first estimate the solutions of

\[
\begin{align*}
\partial_t R_c &= L_1 R_c + \varepsilon^2 \mathcal{E}_c(L_2 R_c + G_1 R) + \varepsilon^2 f_c, \\
\partial_t R_s &= L_1 R_s + L_s R_c + f_s
\end{align*}
\]

with \( \mathcal{E}_c f_c = f_c \) and \( \mathcal{E}_s f_s = f_s \). Using a modification of Lemma 3.2, we obtain for the linear semigroup generated by \( L_1 \) the estimate

\[
\|e^{t L_1} \mathcal{E}_c \|_{\mathcal{L}(H_{ul}^j, H_{ul}^j)} \leq C e^{\sigma_0 t},
\]

due to the compact support of \( \chi_c^h \) and since \( \text{Re} \lambda_{1,2}(k) \leq \alpha_0 \varepsilon_0^2 \) for \( |k| \in [3/4, 5/4] \). Similarly, for some \( \sigma_0 > 0 \) we have

\[
\|e^{t L_1} \mathcal{E}_s \|_{\mathcal{L}(L_{ul}^2, H_{ul}^j)} \leq \|1 + | \cdot |^2 \|^{1/2} \left( \begin{array}{c} \varepsilon^2 \\ \varepsilon^2 \end{array} \right) \chi_s^h(\cdot) \|_{C^2(\mathbb{R}, \mathbb{C})} \leq C e^{-\sigma_0 (1 + t^{-1/4})},
\]

since \( \text{Re} \lambda_{1,2}(k) \leq -2\sigma_0 \) for \( |k| \not\in [3/4, 5/4] \) and since \( \lambda_{1,2}(k) \sim -k^4 \) as \( |k| \to \infty \). From (3.24),(3.25) follows the local solvability of (23) in \( H_{ul}^j(\mathbb{R}) \). Writing the solutions \( R_c, R_s \) as

\[
R_c(t) = \varepsilon^2 \int_0^t e^{(t-\tau)L_1} (\mathcal{E}_c(L_2 R_c + G_1 R + f_c)) d\tau,
\]

\[
R_s(t) = \int_0^t e^{(t-\tau)L_1} (L_s R_c + f_s) d\tau
\]

and introducing \( S_c(s) = \sup_{\tau \leq s} \|R_c(\cdot, \tau)\|_{L_{ul}^2} \), we obtain

\[
S_c(s) \leq \int_0^s C(1 + (t - \tau)^{-1/4}) e^{-\sigma_0 (t - \tau)} d\tau (S_c(t) + \|f\|_{\mathcal{H}^0})
\]

\[
\leq C S_c(t) + C \|f\|_{\mathcal{H}^0}.
\]

Inserting this into the equation for \( S_c \) shows that

\[
S_c(t) \leq \varepsilon^2 \int_0^t C e^{C \varepsilon^2 (t - \tau)} (C S_c(\tau) + \|f\|_{\mathcal{H}^0}) d\tau.
\]

Gronwall’s inequality gives \( S_c(T_0/\varepsilon^2) = \mathcal{O}(1) \). Thus we have \( J \in \mathcal{L}(\mathcal{H}^0, \mathcal{H}^1) \) for the solution operator \( J \) of (3.23).
Applying $J$ to (3.21) we obtain $R = J\delta + \varepsilon J\tilde{N}(R) =: F(R)$. For $0 < \varepsilon \leq \varepsilon_0$ for some $\varepsilon_0 > 0$ the function $F : \mathcal{H}^1 \to \mathcal{H}^1$ is a contraction on a ball in $\mathcal{H}^1$ with radius $O(1)$ and center $J\delta$ due to the Lipschitz continuity of $\tilde{N}$ and the factor $\varepsilon$ in front $J\tilde{N}$. Thus there exists a unique fixed point which is a solution of order $O(1)$ of (3.21). Using (3.17) and $\|\varepsilon\Psi_2 - \varepsilon\Psi_0\|_{\mathcal{H}^1} = O(\varepsilon^2)$ the proof of Theorem 3.1 is complete.
